CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937. 3:00 P.M. (E.T.)

GENERAL CROP REPORT AS OF JULY 1, 1937.

Crops are off to about an average start according to the July estimates of the Crop Reporting Board of the United States Department of Agriculture.

About the usual acreage of crops is expected to be harvested and moderately favorable growing conditions now prevail over most of the country except portions of the Great Plains area, where rain is urgently needed. Unless present forecasts are upset by unusual weather conditions during the remainder of the growing season, the production of the principal crops will be much greater than in the recent drought years, 1933, 1934 and 1936, and about equal to the average production during the 1928-32 period preceding. On the whole, the production of most crops may now be expected to meet prospective needs, so far as needs can be calculated when allowance has to be made for population growth, increasing industrial requirements, changing export outlets, reduced numbers of grainconsuming livestock on hand, and depleted reserves in grain bins, corn cribs and haymows.

With winter wheat being harvested and spring wheat production still very uncertain because of the threat of serious loss from rust, the total wheat crop is estimated at 882,000,000 bushels. This would be the largest wheat crop since 1931, but reserves are low and some wheat will be needed for feeding livestock until new corn can be harvested.

The corn crop is urgently in need of rain in the Great Plains area, has been hurt by dry weather in parts of the South and was planted late in some northern areas, but it is growing well in the central and eastern portions of the Corn Belt and production in the United States is expected to be around 2,572,000,000 bushels. This would be the third largest corn crop since 1928 but less than the average production during the 10 previous years. A corn crop of the size now estimated, plus the about-average crops of oats, barley and grain sorghums expected, the low record carry-over of feed grain on farms, and a rough allowance for wheat to be fed, would give slightly more than the usual supply of feed grain per head of livestock to be wintered.

Current reports on hay show prospects for about the usual acreage and yield this season but a light supply of old hay on hand, indicating a total hay supply of about the usual tonnage and about the usual quantity per head of hay-consuming livestock. However, the feeding value of the hay produced is likely to be below average due to wet weather during the haying season and extensive loss of new clover seedings during the drought last year.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937 🗼

July 1, 1937.

3:00 P.M. (E.T.)

Pastures are excellent in all States from Minnesota and Missouri eastward and also in most of the area west of the Rockies, but they are still distressingly poor along a wide belt extending from central Montana into western North Dakota and down to south Texas. In the country as a whole, the condition of pastures averaged 79.4 which represents a great improvement over the 58.1 average of a year ago and is higher than the condition on the same date in six of the last seven years, but below the usual July 1 conditions prior to 1930.

The indications for the food crops, other than wheat, show rather large supplies in prospect, for when the figures for 1937 are compared with the 1928 to 1932 average, a number of crops show increases considerably exceeding the estimated increase in population. The estimated increases for potatoes and beans are about 8 percent, sweetpotatoes and sugar beets about 10 percent, and rye and rice 32 and 14 percent respectively. A rather large acreage of peanuts has also been planted. The fruit crops are expected to be good. Apples, pears, grapes, cherries, and apricots are each showing production greater than the 1928-32 average by 14 percent, and although peaches and prunes are expected to be only about average, the estimated total tonnage of all these fruits combined shows an increase of nearly 14 percent over the 5-year (1928-32) average, and an increase of 16 percent over production last year. The citrus and nut industries are also expanding. Due to last winter's freezes in California, only a moderate supply of oranges will be available this summer, but after fruit from this year's bloom comes on the market next fall the supply of citrus fruits is expected to be fully up to the large production of the last 12 months. An increase in orange production is expected to offset moderate decreases in grapefruit and lemons. Record crops of walnuts and almonds are expected. Vegetable crops are expected to show rather irregular increases due to the planting of larger acreages and to rather favorable growing conditions up to July 1. The weather has been particularly favorable for fall cabbage, but the heavy rains of the last half of June caused some damage to the celery and onion crops of the North Central States.

The acreage of tobacco is nearly 18 percent larger than the rather low acreage last year, but even though yield prospects are rather favorable, the indicated production is not above production during the 1928 to 1932 period. With the increasing demand and moderate stocks, supplies of most types are not expected to be excessive.

The acreages of soybeans and cowpeas show further expansion of 7 and 8 percent this year. Excluding the large acreages interplanted with corn in the South, soybeans are being grown on more than 6,000,000 acres, and cowpeas on more than 3,500,000, the acreage in each case being about double the 1928-32 average.

High feed costs this season have led to sharp culling of hens and to an abnormally small hatching of chicks, but the hens were laying unusually well on July 1 and daily egg production in the United States was about 2 percent heavier than at the same season last year.

Milk production on July 1 represented about the usual per capita supply for that season but was around 3 percent higher than on the same date last year when drought and hot weather were reducing the milk flow. Excellent pastures have maintained milk production in important dairy sections and good prices for dairy products have encouraged early weaning of calves in areas where many cows of beef and dual purpose type are milked.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937 July 1, 1937. 3:00 P.M. (E.T.) 3:00 P.M. (E.T.)

WHEAT: A total United States wheat production in 1937 of 882,287,000 bushels is indicated by condition on July 1. Production of wheat in 1936 was estimated at 626,461,000 bushels and the 5-year (1928-32) average was 864,532,000 bushels.

Indicated production of winter wheat is 663,641,000 bushels, compared with 519,013,000 bushels produced in 1936 and the 5-year average production of 623,220,000 bushels. The present indication is somewhat higher than that of a month ago. Preliminary threshing returns indicate that yields are turning out somewhat better than expected quite generally except in the area extending from Nebraska and Kansas to Ohio, where prospects were reduced by rust. Stem rust was first observed in eastern Kansas and Nebraska early in June and spread eastward as far as Ohio, causing varying degrees of damage in all these States. In most of the hard red winter wheat area, rains late in May and early June brought about substantial improvement in prospects but the improvement was not sustained except in early harvesting areas.

The acreage of winter wheat harvested or to be harvested is now estimated at 47,079,000 acres compared with 37,608,000 acres harvested in 1936 and the 5-year (1928-32) average of 39,724,000 acres.

Indicated production of all spring wheat is 218,646,000 bushels, a sharp increase over the 107,448,000 bushels produced in 1936 but well below the 5-year (1928-32) average of 241,312,000 bushels. In the western part of the principal spring wheat area, growing conditions were decidedly unfavorable early in the season. While considerable improvement was brought about by June rains, this area is still deficient in moisture supplies. Prospective yields are below average quite generally except in the Pacific Northwest.

In the Dakotas, Nebraska, and western Minnesota, a light but widespread infection of stem rust is a threatening factor. Visible damage to the crop has been slight, but if weather conditions should be favorable for rust development, serious losses would result. In interpreting the July condition figures, the Board has made allowance for probable losses from rust, as indicated by a study of the relation between July condition and final outturn in other years when growing conditions and the presence of rust were comparable to this year. With the crop somewhat later than usual, there is room for considerable improvement in prospects if the rust does not develop. On the other hand, losses might be greater than are anticipated at present.

Since July 1, above normal temperatures with only small amounts of precipitation have been unfavorable to rust development, but have also caused fear of heat damage, especially in the drier areas.

The acreage of spring wheat for harvest this year, 21,119,000 acres, is nearly twice as great as the 11,212,000 acres harvested last year and is above the 5-year (1928-32) average of 20,414,000.

This acreage makes allowance for abandonment indicated on July 1. indicated seeded acreage is about 23,500,000 acres compared with 23,912,000 acres seeded in 1936 and the 5-year average seeded acreage of 22,121,000 acres.

Stocks of old wheat on farms on July 1, 1937, were estimated at only 21,880,000 bushels compared with 43,988,000 bushels on July 1, 1936, and 44,339,000 bushels on July 1, 1935, following the short crop of 1934. mjd -5-

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937.

The acreage of corn for harvest is reported at 96,146,000 acres, an increase of 3.6 percent over the 92,829,000 acres harvested in 1936. The 1935 acreage was 95,804,000 and the 5-year (1928-32) average 103,419,000 acres. General increases in the acreage for harvest, ranging from moderate in the important North Central States to large in the upper Great Plains States much more than offset the decreased acreage in the Southern States and Missouri. Short feed supplies, high prices and a fair to good planting season were the main factors influencing an increase in the acreage for harvest this season. The total acreage planted to corn was about 4 percent less than that of a year ago, but in 1936 drought, heat and insect damage resulted in drastic reductions in the acreage remaining for harvest in some areas.

The indicated production of corn is estimated at 2,571,851,000 bushels compared with 1,529,327,000 bushels in 1936, and the 5-year (1928-32) average of 2,554,772,000 bushels. July 1 condition of corn at 82.1 percent is above the 10-year (1923-32) average condition of 79.5 percent and compares with 72.8 percent a year ago. The indicated yield per acre is 26.7 bushels compared with the final yield of 16.5 bushels in 1936 and the 10-year (1923-32) average of 25.4 bushels.

The July 1 corn prospect is the most favorable since 1932 except in the Western Great Plains States where conditions vary from average to sharply below average because of drought and insects. Stands are good and condition is a bove average in the leading corn States, wet field conditions in many States resulted in a rather late start, but later planting conditions were satisfactory, permitting the completion of planting only moderately later than usual.

Stocks of old corn on farms July 1, 1937 are the lowest on record and estimated to be 156,113,000 bushels, or 12.4 percent of 1936 corn for grain production. This compares with 394,794,000 bushels on farms a year ago and the 5-year (1928-32)

average of 374,078,000 bushels for July 1.

OATS: The production of oats in 1937 is indicated at 1,111,229,000 bushels which is about 41 percent more than the 1936 crop of 789,100,000 bushels. The crop as indicated by the July 1 condition of 83.8 percent is, with exception of 1935, the largest since 1932. The 5-year(1928-32) average production was 1,215,102,000 bushels. The 35,933,000 acres reported for harvest as grain this year is 8.2 percent greater than the 33,213,000 acres harvested in 1936 but is 4,082,000 acres less than the 5-year (1928-32) average acreage.

The increase in this year's indicated acreage for harvest over that harvested last year is due in large part to the heavy loss of acreage because drought in 1936. Abandonment last year was above average in the Great Plains States and particularly severe in the Dakotas. The reported acreage for harvest this year makes allowance for the abandonment indicated by July 1 condition. The acreage seeded this year was about 36,400,000 acres compared with 39,625,000 acres seeded in 1936.

The indicated yield of 30.9 bushels per harvested acre for 1937 is much above the 1936 yield and compares with the 10-year (1923-32) average of 30.2 bushels per acre. Growth of the crop in the North Central States, east of the Missouri River has been unusually good and excellent yields are in prospect. Yields considerably above average were obtained in the Southern States with the exception of Oklahoma and Texas. The only area where prospective yields are below average is that extending from Montana and North Dakota southward through Texas.

Farm stocks of oats on July 1, 1937 were estimated at 88,474,000 bushels which compares with 287,745,000 bushels estimated on April 1, 1937 and 246,952,000 bushels on July 1, 1936. The 5-year (1928-32) average farm stocks on July 1 is

148,516,000 bushels.

BARLEY: The production of barley in 1937 is indicated at 243,540,000 bushels which compares with 147,452,000 bushels produced in 1936 and the 5-year (1928-32) average production of 281,237,000 bushels. The condition on July 1 was 79.3 percent of normal indicating a yield of 21.8 bushels per harvested acre as compared with 17.7 bushels in 1936. The 10-year (1923-32) average yield per acre of barley is 22.6 bushels. Indicated yields are slightly below average in most of the North Central and Western States where sub-normal conditions prevail as a result of continued drought. mjd

GROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937.

The 11,166,000 acres of barley to be harvested as grain is about 34 percent more than the 8,322,000 acres harvested in 1936 but 12 percent below the 5-year (1928-32) average of 12,645,000 acres. Seeded acreages were below average in nearly all North Céntral and Western States east of the Continental Divide where the 1936 drought was most severe and consequently seed supplies were short this spring. North Dakota is expected to harvest 1,761,000 acres and South Dakota 1,728,000 acres, both of which are below average. The 2,040,000 acres indicated for Minnesota is slightly above average.

RYE: Rye production in 1937 is indicated at 50,398,000 bushels, or about double the light production of 25,554,000 bushels in 1936. The 1935 crop was 58,597,000 bushels and the 5-year (1928-32) average is 38,212,000 bushels.

The acreage of rye for harvest as grain is indicated to be 3,960,000 acres, an increase of 43.6 percent over the 2,757,000 acres harvested in 1936, and, with the exception of 4,141,000 acres harvested in 1935, is the largest acreage since 1923. Nebraska is the only important rye State showing a decreased acreage. The increased acreage this season is widespread and especially large in the leading rye States of the Northwest. North Dakota acreage at 890,000 acres is double that of last year.

Rye condition on July 1 at 76.9 percent indicates a yield per acre of 12.7 bushels compared with 9.3 bushels in 1936 and the 10-year (1923-32) average of 12.0 bushels. Nearly all States report good stands where fields were not over-grazed and fair to good yields are expected rather generally.

FLAXSEED: A 1937 flaxseed crop of 7,622,000 bushels is indicated by the July 1 condition. This compares with 5,908,000 bushels produced last year, 14,520,000 bushels in 1935 and the 1928-32 average of 15,996,000 bushels. The small crop indicated this year is primarily the result of decreased acreage. All major flaxseed States show reductions in the crop, with the Dakotas and Montana making the greatest declines. The production indicated for Minnesota is 4,246,000 bushels, which is slightly above the 1936 crop but only 70 percent of the 5-year (1928-32) average. North Dakota, with a 5-year average production of 5,944,000 bushels, will harvest but 1,796,000 bushels this year according to the July 1 condition. South Dakota and Montana flaxseed production is indicated at 270,000 and 40,000 bushels respectively, which compare with averages of 2,170,000 and 1,149,000 bushels.

The indicated acreage of flaxseed for harvest in 1937 is 1,081,000 acres, which is a decrease of 8 percent from 1,180,000 acres harvested last year and is but 39 percent of the 5-year average acreage. The Minnesota acreage for harvest is but 63 percent of the 1928-32 average, North Dakota 37 percent, South Dakota 13 percent, and Montana only 4 percent. Although allowance for abandonment was made in the indicated acreage for harvest in 1937, the acreage seeded is far below that of last year. Approximately 1,400,000 acres were seeded this year as compared with 2,500,000 acres in 1936.

The condition of 73.7 percent on July 1 for the United States indicates a yield of 7.1 bushels per acre on the acreage left for harvest. This compares with 5.0 bushels last year and the 10-year (1923-32) average of 6.9 bushels.

HOPS: With a condition of 83.2 on July 1, and an acreage of 35,100 acres, a production of 44,720,000 pounds of hops is indicated compared with 23,310,000 pounds last year, and the 5-year (1928-32) average of 28,011,000 pounds. The report shows an increase of 3,600 acres over the area harvested in 1936, and 12,000 acres more than the acreage harvested during the 5-year period.

CROP REPORT as of July 1, 1937.

percent.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937 6 3:00 P.M. (E.T.) Saly 1, 1997.

TO BACCO: The 1937 tobacco crop is indicated at 1,420,943,000 pounds which would be about 23 percent larger than the 1936 crop, but about equal to the 5-year (1928-32) average production. The acreage set this year is reported to be 1,689,700 acres, or 17.6 percent more than that harvested last year, although about 10 percent less than the 5-year (1928-32) average acreage and about 20 percent less than the record acreage harvested in 1930. Acreage increases compared with last year are reported for all States, except Georgia and Maryland. The condition of the crop is reported as 73.4 percent of normal as of July 1, com-

The acreage of flue-cured tobacco is about 11 percent larger than that harvested last year and the indicated production is 767,215,000 pounds. would be about 13 percent more than the 1936 crop and about an equal percentage more than the 5-year (1928-32) average production, although about 5 percent less than the 1935 crop and 11 percent less than the record crop produced in 1930.

pared with 57.1 percent last year and the 10-year (1923-32) average of 75.3

An increase of 11 percent compared with the record low acreage last year of fire-cured tobacco is also shown. The production of this class of tobacco is indicated at 114,635,000 pounds, compared with 99,666,000 pounds last year and the 5-year (1928-32) average production of 160,588,000 pounds.

The acreage of Burley tobacco is reported at 420,600 acres, which is an increase of 40 percent over the 301,300 acres harvested last year. Production of this class of tobacco is indicated at 360,830,000 pounds, which would be about 65 percent more than the 1936 crop and about 7 percent more than the 5-year (1928-32) average production, but about 15 percent less than the record crop produced in 1931 and 4 percent less than the 1933 crop.

Maryland tobacco acreage is about 4 percent less than that harvested last year, and production is indicated at 23,075,000 pounds, compared with 29,600,000 pounds last year and the 5-year (1928-32) average production of 24,318,000 pounds.

The acreage of dark air-cured tobacco is reported at 48,400 acres, or an increase of 42 percent compared with 34,200 acres harvested last year. Production is indicated at 42,750,000 pounds compared with 24,646,000 pounds harvested last year and the 5-year (1928-32) average production of 54,111,000 pounds.

Cigar tobacco acreage shows an increase of 18 percent compared with last year. The increase by classes is distributed as follows: filler 11 percent, binder 29 percent and wrapper 13 percent. The total production of these classes of tobacco is indicated at 112,438,000 pounds, which would be about 15 percent more than the 1936 crop, but about 35 percent less than the 5-year (1928-32) average production.

DRY EDIBLE BEANS: The production of dry edible beans, estimated at 13,163,000 bags is 2,041,000 bags larger than the 1936 crop and 982,000 bags above the 5-year (1928-32) average. The factors contributing to the prospective increase in production are the 14.9 percent increase over last year in acreage, and an increase of 22 pounds per acre in the indicated yield. The greatest increases in prospective production are in Michigan and California. Substantial increases over last year are expected to occur in the States of Montana, Idaho, Wyoming, Colorado and New Mexico in most of which there was considerable loss of acreage in 1936 due to drought.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937

July 1, 1937

3:00 P. M. (E.T.)

Production of beets for sugar is indicated at 8,952,000 short tons compared with 9,028,000 harvested in 1936, and the average of 8,118,000 short tons for the five years 1928-32. No report of probable beet-sugar production is made at this time.

The indicated acreage for harvest is 778,000 acres, which is about the same as 1936 and 8 percent larger than the average harvested acreage during the 5-year (1928-32) period, but about 21 percent below the record high acreage of 983,000 acres harvested in 1933.

The Mountain States of Colorado, Wyoming, Utah, Montana, and Idaho combined show an increase of 20,000 acres over the acreage harvested in 1936. On the other hand, this increase is more than offset by the decrease of 24,000 acres in eastern territory and in the Great Lakes region. Nebraska shows a decrease of 6 percent in acreage, while the acreage for harvest in California is unchanged from that of last year.

The growing condition of sugar beets on July 1 was 84.2 percent of normal. This is about the 10-year average condition on that date and points to an average yield of 11.5 tons per acre.

The California crop is progressing rapidly after a late start. Early fields were retarded by wet and cool weather. Colorado stands of sugar beets are generally good, and the crop has made satisfactory growth to date. The crop got a late start in Utah, and stands are mostly fair. Irrigation water is in ample supply in most of the sugar beet producing States.

CANE SIRUPS: In the sixteen States growing sorgo for sirup 198,000 acres are reported for harvest compared with 215,000 acres harvested last year and 201,000 acres, - the 5-year (1928-32) average. The decrease of 17,000 acres in the area for harvest this year is chiefly in Tennessee, Arkansas, Mississippi, and Alabama. report of sorgo sirup production is made at this time.

The acreage of sugar-cane for sirup in eight States, including Louisiana, is placed at 138,000 acres compared with 140,000 acres harvested in those States last year. No report of probable production of sirup is made at this time for any State excepting Louisiana. A production in Louisiana of 7,125,000 gallons is indicated. Last year Louisiana produced 7,729,000 gallons.

In Louisiana a crop of 5,216,000 short tons of sugarcane is indicated by the condition of 86 percent on July 1, on an acreage for harvest of 287,000 acres. Last year the production of sugarcane was 5,641,000 tons cut from 272,000 acres. The 5-year (1928-32) average is 3,006,000 tons and 214,000 acres. Planters' reports indicate a production for grinding of about 4,512,000 tons for sugar and 338,000 tons for sirup, which if realized would yield about 376,000 short tons of sugar (raw value, 960 test), and 7,125,000 gallons of sirup. Production last year was 386,000 short tons of sugar (raw value, 96° test), and 7,729,000 gallons of sirup. Cold, wet weather in the spring, followed by drouth in May, hindered somewhat the early development of the cane; but July 1 found the crop making very satisfactory progress after frequent showers accompanied by seasonal high temperatures that promoted rapid growth.

CROP REPORT

CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937. 3:00 P.M. (E.T.)

FRUIT AND MUT SUMMARY: Most of the deciduous tree and vine fruits have developed under favorable conditions during the 1937 season and indications on July 1 point to above-average crops of apples, peaches, pears, grapes, cherries, and apricots. Total production of plums and prunes for all purposes is slightly below average. The combined prospective production of the above crops for the 1937 season is 16 percent larger than production of these crops in 1936 and is 14 percent above the 5-year (1928-32) average production. For walnuts and almonds (the only tree nuts on which indications are available at this date) the 1.937 indicated production is the largest on record. Condition of citrus fruits from the bloom of 1937 is variable, with prospects of an orange crop for the 1937-38 marketing season somewhat larger than the 1936-37 production and of a grapefruit crop smaller than the record high production of 1936-37. Lemon prospects from the 1937 bloom are at present uncertain but the low condition of July 1 points to a small crop. The supply of oranges for marketing during the summer months of 1937 is relatively small; the supply of lemons appears to be somewhat smaller than was available last summer.

With the exception of freeze damage to peaches in some of the Southern States, deciduous trees and vines, for the most part, came through the winter without serious damage to the fruit buds. The bloom was heavy in most areas, the set of most fruits was good, and an abundant moisture supply has been favorable for the development of most of these fruits.

APPLES: Prospective production of apples in 1937 is the largest since 1931. The July 1 indicated production of 194,328,000 bushels in 1937 is 65 percent larger than the unusually small crop of 117,506,000 bushels in 1936 and is 18 percent above the 5-year (1928-32) average production of 164,355,000 bushels. Condition of the crop on July 1 was 70.2 percent of normal compared with 42.6 percent on July 1, 1936, and with the 10-year (1923-32) average condition of 59.8 percent.

The reported condition indicates larger-than-average crops in all geographical sections except the Western States. Present prospects in this group, including the Rocky Mountain and Pacific Coast States, are for a crop 10 percent less than average but about 10 percent larger than production in 1936. Cool, rainy weather during blossom time interfered with pollination in important areas of the Western States and reduced the set of fruit to some extent. Unusually good crops of apples are indicated in the North Atlantic, South Atlantic, South Central and the North Central groups of States. In some States in the western half of the North Central group, however, the apple crop is below average because of loss in vitality of trees from the 1936 drought.

For the country as a whole, growing conditions during June were favorable for the development of the apple crop. With an abundance of moisture during the month, fruit is reported as of good size but scab is becoming more prevalent in the important apple areas of the East and Middle West. In Washington and Oregon aphis damage is reported to be above average but codling moth activity to date has been below average. Rainy weather during June in these States, however, washed off the protective sprays and increased the possibility of future moth damage. In California a good crop of Gravensteins is indicated in the Sebastopol area and of late varieties in the major commercial area.

PEACHES: The total peach crop in the United States is indicated by the July 1 condition at 57,693,000 bushels compared with 47,650,000 bushels produced in 1936 and with the 5-year (1928-32) average production of 57,298,000 bushels.

GROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937

July 1, 1937. пония вышания вышания на выстрания вышания на вышания вышания вышания вышания вышания вышания вышания вышания в

3:00 P.M. (E.T.)

While prospective production for the United States is 21 percent larger than the quantity produced in 1936, it is only slightly larger than the 5-year average production.

Growing conditions were favorable in most important peach areas during June, and the indicated production is now about 3 percent greater than was reported a month ago. Nearly all of the more important producing States recorded gains during the month. Fruit has sized well, except in some instances where the set is very heavy. There is less than the usual amount of disease, and in general the fruit is clean and promises good quality. In the late producing States, where maturity is from one to two months distant, the present moisture supply is good.

In the 10 Southern States the July 1 indicated production for the group is 11,247,000 bushels, or 23 percent below the 5-year average production. This is somewhat larger than was indicated on June 1. Increases over the indicated production of a month ago are reported in all States in this group with the exception of Louisiana and Texas. Georgia has a crop only 41 percent of average, and the crops in South Carolina, Alabama, Mississippi, and Texas are somewhat below average. North Carolina has nearly an average production. Arkansas and Oklahoma have crops much above average.

In the North Atlantic group of States prospective production is considerably above the 5-year (1928-32) average production due to the exceptionally good prospects in New York, New Jorsey, and Ponnsylvania. Heavy production is indicated for Virginia and Delaware. The outlook is unusually favorable in Kentucky, Tennessee, Missouri, Michigan, and Ohic, and Illinois has a somewhat better than average crop.

In the West, production in Colorado is somewhat larger than in 1936 and much above the average production. In California, indicated production is below average for both clingstone and freestone varieties but slightly above the production of 1936. Washington has a crop about one-half of that produced in 1936 and considerably below average. The indicated production in Oregon is about average, but near failures are reported for Idaho and Utah.

Total pear production for the 1937 season, based on the July 1 condition of 62.1 percent, is indicated at 30,178,000 bushels compared with the 1936 crop of 26,956,000 bushels and with the 5-year (1928-32) average of 24,334,000 bushels. In spite of a 4 percent decline in prospects since June 1, indications point to a total pear production well above that of any previous season.

In the North Atlantic group of States, with the exception of Pennsylvania, the set was light. In Pennsylvania the June drop was relatively light and prospects are for a pear crop considerably above average. In the North Central group prospects are above average in all States. Although considerable pear blight is reported in Ohio and Illinois and a heavy drop in Michigan, good pear crops are expected in these States. Prospects in the other States of this group are unusually good. In the South Atlantic States indications point to good pear crops except in Georgia and South Carolina, where production is below average because of damage from spring freezes. Some improvement is shown in the South Central States since June 1 and the indicated production for this group is now about equal to the 5-year average. In the Pacific Northwest condition is variable.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937

July 1, 1937

3:00 P. M. (E.T.) <u>полительности под применення в применення </u>

Continued cool, wet weather during June resulted in considerable blight and scab damage but the indicated production is the largest of record. Worm damage to date is negligible. Condition of the California pear crop remains unchanged. Prospective production is above average, with Bartletts showing up relatively more favorable than fall or winter varieties.

GRAPES: Production of grapes in 1937, as indicated by condition of the crop on July 1, is the largest since 1928. The indicated crop of 2,526,670 tons is 32 percent larger than the 1936 production of 1,916,460 tons and 14 percent above the 5-year (1928-32) average of 2,214,482 tons.

The California grape crop developed under favorable conditions during June and indications point to a production of 2,219,000 tens of all grapes compared with a crop of 1,714,000 tons in 1936 and with the 5-year average of 1,924,000 tons. The condition of wine grapes declined slightly from that of June 1, but good prospects are reported in nearly all producing areas. Condition of table grapes remains unchanged from that of June 1, with favorable prospects in the important producing sections of the San Joaquin Valley. Raisin grape varieties are relatively later than in most seasons. No serious heat damage nor excessive outbreaks of grapeleaf hopper have been reported in the major raisin-producing areas and the indicated production is the largest since 1928. Grape prospects in New York, Pennsylvania and Michigan are below the 5-year average. Indications point to a large grape crop in Ohio and to above-average crops in Missouri and Arkansas.

CHERRIES: The total crop of all cherries (both sweet and sour varieties) in the 12 commercial States is indicated to be 144,610 tons compared with the 1936 production of 115,160 tons and with the 5-year (1928-32) average of 116,704 tons. The July 1 indication of 144,610 tons is 9 percent less than that of June 1 because of losses caused by heavy rains in some of the Western States.

Prospects in the Pacific Northwest and in Idaho are considerably lower than a month ago. June rains, which came as the crops were maturing, caused considerable splitting of fruit, and the outlook for sweet varieties in these States is uniformly poor. Sour cherries in general escaped serious injury as they reached maturity after most of the rains were over. In the eastern States (New York, Pennsylvania, Ohio, Michigan and Wisconsin) the general outlook is for excellent cherry crops of the sour varieties. Sweet cherry production in these States is a relatively small part of the total crop. The sweet cherry crop in Utah is poor as a result of rains during pollination. Sour cherries, however, bloomed during a period of dry weather and a good crop of this variety is in prospect. The estimated production in Colorado is slightly less than was indicated on June 1 but is above average. Production in California, where harvesting is about over, is somewhat larger than indicated on June 1 but is smaller than the crop of 1936.

CITRUS FRUITS: The July 1 condition of oranges in California and Florida from the bloom of 1937 is slightly below the 10-year (1923-32) average. Compared with July 1, 1936, the condition of California oranges is only 1 point lower, and in Florida it is much higher. Condition of Valencias in California is higher than condition of Navels. Texas orange condition is below that of last year but is well above that of the two previous years. In California it is difficult to estimate the final set of fruit as it is probable that many trees may not have the usual vigor to develop the fruit because of freeze damage last January. In Florida moisture conditions for the coming crop are favorable at the present time as a result of abundant rains in late June. In Texas there was practically no rainfall during June and irrigation was necessary in all areas.

ces

CROP REPORT

DUREAU OF AGRICULTURAL ECONOMICS

CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937. 3:00 P.M. (E.T.)

With the exception of Arizona, the July 1 condition of grapefruit from the bloom of 1937 is only fair and is much below the condition reported on July 1, 1936. In Florida the July 1 condition is only 50 percent of normal compared with the 10-year (1923-32) average of 72 percent. Trees in this State are mostly in a flourishing condition but the late bloom has been very light. Trees in Texas, for the most part, are reported in good condition and the fruit is reported to be larger in size and farther advanced than at this time last year. The decline in condition from May to June this year, however, was slightly greater than the decline during the same period last year. Condition of the California crop has also declined considerably since June 1 as a result of a lighter set of fruit in evidence in Coachella and Imperial Valleys. The condition of Arizona grapefruit is good.

The July 1 condition of California <u>lemons</u> from the bloom of 1937 is only 58 percent compared with the 10-year (1923-32) average of 79 percent. Since lemons blossom over a long period of time, it is difficult at present to evaluate the crop set. Much of the usual early spring blossom did not set but it is possible that the later bloom may partially compensate for the light set of early fruit.

The indicated production of <u>oranges</u> for the 1936 season (from 1936 bloom) totals 52,219,000 boxes compared with 52,213,000 for 1935-36 and with the 5-year (1928-32) average of 48,816,000 boxes. As the picking season of California Valencias advances, it appears that a crop of about 15,600,000 boxes will be harvested compared with 18,580,000 boxes in 1935-36. Total production of <u>grapefruit</u> from the bloom of 1936 is indicated at 29,751,000 boxes compared with 18,329,000 boxes in 1935-36 and with the 5-year (1928-32) average of 14,730,000 boxes. Total <u>lemon</u> production from the bloom of 1936 (harvested and to be harvested) is larger than previously indicated since the freeze damage of last January and probably will amount to 7,663,000 boxes compared with 7,787,000 in 1935-36 and with the 5-year (1928-32) average of 7,251,000 boxes.

PLUMS AND PRUNES: Production of plums and prunes for fresh use and for canning in the 5 important States of California, Oregon, Washington, Idaho, and Michigan, is indicated at 122,700 tons compared with 139,400 tons in 1936 and with the 5-year (1928-32) average of 134,900 tons. The indicated production of prunes for drying in California, Oregon and Washington totals 223,600 tons (dry basis) compared with 184,300 tons in 1936 and with the 5-year average of 226,140 tons.

In Michigan, prospective <u>plum</u> production is above average, although rains have caused considerable brown rot. The California <u>plum</u> crop is somewhat smaller than the 1936 production and is below the 5-year average as the result of an irregular set of fruit. Production of <u>prunes for drying</u> in California is much larger than in 1936 and is somewhat above average. In Idaho, dropping of <u>prunes</u> has been unusually heavy and is still continuing. In Washington and Oregon prune prospects are quite variable and exceptionally small crops for drying and canning are indicated. Prospects east of the Cascade Mountains in these States, where the crop is largely marketed for fresh use, are relatively more favorable than in the drying and canning areas.

MISCELLANEOUS FRUITS AND NUTS: The July 1 indicated production of <u>California</u> apricots remains unchanged from that of June 1. Prospective production totals 285,000 tons, which is about 3 percent larger than the record crop of 1931, and is 25 percent above the 5-year (1928-32) average. Production in 1936 was 248,000 tons. The <u>Walnut</u> crop developed under favorable conditions during June and a record crop is indicated.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937.

Production is placed at 56,000 tons; the 1936 crop totaled 41,900 tons. Almond production is indicated at 15,300 tons compared with the 1936 crop of 7,600 tons and with the 5-year (1928-32) average of 12,200 tons. Most of the important almont producing areas are showing an exceptionally heavy crop. Olives bloomed heavily in most localities but the set of fruit was irregular. Fig prospects in California are good in all areas, but it is too early for definite indications on probable production. In Oregon, walnut prospects are favorable, since June rainfall resulted in no unusual damage. Trees, however, still show the effect of the 1935 freeze. Filberts set well and present prospects are for a heavy crop.

POTATOES: The July 1 condition of the potato crop is reported at 83.3 percent of normal, with an indicated production of 404,229,000 bushels. If present prospects are realized, it will be the fifth largest potato crop of record - the largest was 427,249,000 bushels harvested in 1928. Estimated production in 1936 was 329,997,000 and the 5-year (1928-32) average production, 372,115,000 bushels. The indicated potato acreage for harvest this year is 3,223,900 acres or nearly 6 percent more than the 1936 harvested acreage. However, it is 3 percent less than the average acreage harvested during the 5 years, 1928-32. Average yield indications on July 1 were 125.4 bushels per acre compared with 107.9 in 1936, and a 10-year (1923-32) average of 112.7 bushels.

While planting of the late crop was delayed somewhat in many Northern States on account of a wet, backward season, these weather conditions were generally ideal for the growing crop. Potato vines are generally heavy and growing vigorously in most of the important northern areas from Maine to the Pacific coast. In the North Central States, some late planted seed has rotted in the ground because of the heavy June rains.

The indicated production on July 1 in each of the 18 Surplus Late States is above the 1936 production estimates. In the 30 Late States, the indicated production is 328,972,000 bushels compared with 277,710,000 in 1936 and the average production of 300,186,000 bushels. Production in the 7 Intermediate States is expected to be 38,419,000 bushels which is approximately 12,000,000 bushels more than these States harvested last year. The harvest of the early farm and commercial crops is practically over in the 11 Early States where the indicated production this year is 36,838,000 bushels or nearly 11,000,000 bushels above last year's estimated crop and about 4,000,000 bushels above average production.

A sweetpotato production of 72,706,000 bushels in 1937 is indicated by the July 1 reported condition of 73.8 percent. This is 13 percent greater than the 1936 harvested production of 64,144,000 bushels, and 10 percent above the 5-year (1928-32) average of 66,368,000 bushels. Weather conditions this season have been unusually favorable for the growth of sweetpotatoes throughout most of the important producing areas. The United States indicated yield per acre of 88.0 bushels in 1937 compares with 78.0 bushels per acre in 1936, and the 10-year (1923-32) average yield of 88.5 bushels.

Sweetpotato acreage in 1937 is estimated to be 826,000 acres. This is a slight increase over the 822,000 acres harvested in 1936, and 7 percent greater than the 5-year (1928-32) average of 771,000 acres. Acreage decreases in Delaware, South Carolina, Mississippi, Arkansas, Oklahoma, and Texas were offset by the larger acreage planted in other producing States.

CROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937. 3:00 P.M. (E.T.)

The 1936 shipping season is about over, with the few old/sweetpotatoes left, coming mainly from New Jersey, Delaware, North Carolina and Tennessee. Some shipments of new sweetpotatoes have already started from Alabama and movement is expected to become moderately heavy by the middle of July. New sweetpotatoes for market will be available from Louisiana and Florida about the first week in August.

SOYBEANS: The acreage of soybeans grown alone for all purposes, is 6,049,000 acres. An increase of 15 percent in the acreage in the North Central States represents plantings to supply hay and forage where last summer's drought damaged clover and alfalfa seedings. South Atlantic and South Central States are growing about 10 percent smaller acreage of soybeans alone than last year.

COWPEAS: The expected acreage of cowpeas grown alone of 3,520,000 acres is 7.9 percent larger than in 1936 and the largest acreage on record. The increase is general in all sections, and represents increased plantings for hay and forage in the North Central States, and in the Southern States a shift from soybeans to cowpeas for hay, forage and soil improvement purposes.

<u>VELVET BEANS:</u> The acreage of velvet beans grown alone declined from 158,000 in 1936 to 141,000 acres this year, a decline of 10.8 percent.

The acreage of peanuts, soybeans, cowpeas and velvet beans shown in the report does not include the large acreages of these crops grown with corn and other crops in the Southern States. The proportion of these crops to be harvested for the nuts, beans, or peas is yet to be determined.

PEANUTS: The acreage of peanuts grown alone for all purposes, estimated at 2,016,000 acres, is 1.9 percent lower than last year but 18 percent above the 5-year (1928-32) average. In the Virginia-North Carolina and Georgia-Alabama areas an increase of slightly over 3 percent is indicated, this increase being more than offset in the States from Mississippi westward by decreases exceeding 10 percent.

The July 1 condition of 75.5 percent is 5.3 points higher than on that date last year, but 2.3 points lower than the 10-year (1923-32) average. The condition is above last year in all States excepting Oklahoma and Texas.

RICE: A production of 48,716,000 bushels of rice is indicated from a condition of 86.1 percent on July 1. Last year the production was 46,833,000 bushels, and the 5-year (1928-32) average production is 42,826,000 bushels. An area of 1,003,000 acres is indicated for harvest this year in comparison with 935,000 acres harvested last year, and 925,000 acres, the 5-year average. The increase in California is 14,000 acres over last year. In Texas and Arkansas, together, the estimated increase is 54,000 acres. No change in the acreage from a year ago is indicated for Louisiana.

Stands in Louisiana range from fair to good, but they are for the most part below average because of dry conditions prevailing at seeding time. Fields in some parts of the Louisiana rice belt are menaced by salt water, and some damage has already been done by brackish water. Some of the early planted rice is heading. The crop is reported making favorable progress in Arkansas and Texas. In California the rice crop got a late start this year, but it is now making excellent progress and irrigation water is abundant; the growth is uniform and the stands are good despite the somewhat later than usual seedings.

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., July 9, 1937

3:00 P.M. (E.T.) July 1, 1937. 3:00 P.M. (E.T.)

VEGETABLES: Weather conditions during June were generally favorable for snap beans, cabbage, sweet corn, cucumbers, green peppers, tomatoes, and watermelons. The composite condition of all vegetable crops advanced two points during the past month. A decline in the growing condition of carrots, celery, and onions during this period was caused by heavy June rains, which damaged most vegetable crops growing on muck soil in the north central States.

The harvest of commercial truck crops in the southern States is about over with the exception of watermelons which are now moving in large volume, principally to northern markets. City markets will be supplied during the remainder of July with fresh green vegetables from local market gardens and with commercial vegetable crops which originate chiefly in the intermediate States and central California. During the latter part of July and August vegetable supplies will be available in increasing quantities from the northern States. Vegetable crop prospects are bright in the Pennsylvania-New Jersey-New York area. In the Pacific Northwest vegetables had a late start due to cool, wet weather in May and June but are now growing vigorously.

Total indicated production of hay in 1937 is 85,077,000 tons, from 68,319,000 acres compared with 70,224,000 tons from 67,749,000 acres in 1936 (a drought year); 89,526,000 tons from 68,046,000 acres in 1935, and a 5-year (1928-32) average of 80,065,000 tons from 68,441,000 acres. The July 1 condition of all hay was 80.6 compared with 63.5 in 1936, 83.7 in 1935 and a 10-year (1923-32) average of 78.1.

The larger than usual hay crop indicated for 1937, plus the rather small farm carry-over on May 1, will provide about the usual total supply. Rainy weather made harvesting difficult and probably lowered the quality of early cuttings in the Pacific Northwest and in some of the eastern States north of the Potomac and Ohio Rivers. Indicated yields per acre are near average or better in most States.

Hay acreage is less than in 1936 in most of the northern States from New York to the Missouri River, much of the reduction resulting from drought and winter injury to clover stands. In most other States, the 1937 hay acreage equals or exceeds that of 1936.

Alfalfa hay acreage has continued to expand in most eastern and some western States, but has decreased in part of the Corn Belt because of damage from drought and freezing. Production is expected to be about 28,824,000 tons from 14,177,000 acres compared with 24,750,000 tons from 14,031,000 acres in 1936, and a 5-year (1928-32) average of 23,544,000 tons from 11,720,000 acres.

In the North Central States the clover stands were severely damaged by the drought of 1936 and the winter of 1936-37. In this region, the 1937 acreage of clover-timothy hay is only 79 percent of that harvested in 1936, and in many fields the clover was almost entirely killed leaving only timothy. The indicated production of clover-timothy hay is only 24,296,000 tons from 19,674,000 acres compared with a 5-year (1928-32) average of 30,554,000 tons from 26,872,000 acres. In the drought year 1936, 21,324,000 tons of clover-timothy hay were produced from 22,010,000 acres.

PASTURES: Pastures on July 1 continued to range from poor to distressingly short in a broad central belt extending from eastern Montana and western North Dakota to South Texas. Elsewhere they were good to excellent with the exception of local areas, notably in the Southeast where a possibly temporary decline in pasture condition was caused by the light rainfall of early June. In the country as a whole the condition of pastures on July 1 averaged 79.4 percent of normal. This was much higher than last year's July 1 condition of 58.1 percent and also higher than the condition of the saws dote to six of the last seven years, all seasons of

A. 4 .7.

CROP REPORT

OROP REPORTING BOARD

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937. 3:00 P.M. (E.T.)

poor pastures, but lower than the July 1 condition in twenty-seven of the preceding thirty years.

Pastures, which have improved materially since June 1 in the Northern States, were particularly good in the area extending eastward from the western borders of Minnesota, Iowa, and Missouri, and also west of the Rockies, except in western Montana and north central California. The drought belt was narrowed during June by marked improvement in Wyoming, New Mexico and parts of Montana and the Dakotas, but little, if any, improvement has been shown in Nebraska, Kansas, Oklahoma and Texas and the condition of pastures in those States was about as low as it was on July 1, 1936.

MILK PRODUCTION: Milk production resumed about the normal seasonal trend during June this year following the unusually rapid increases during April and May! Excellent pastures during June in the principal dairy sections have aided in maintaining milk flow at a high level. Where milking herds include many cows of dual purpose type, farmers have been encouraged by the highest June prices for dairy products since 1930 and appear to be making up for the reduced size of their herds by weaning calves earlier and milking a larger proportion of their cows than usual. On July 1 milk production per cow in herds kept by crop correspondents was the highest for that date since 1930 and was between 4 and 5 percent higher than at the same time last year. With between 1 and 2 percent fewer milk cows on farms than a year ago, total milk production on July 1 appears to have been about 3 percent higher than on the same date last year when the effects of the drought on milk production were beginning to be felt. Taking into account the steady increase in population, the per capita production of milk on July 1 was about the same as the 1925-34 average for that date.

The tendency of farmers to milk more than the usual number of their milk cows, noted a month ago, continued through June and on July 1 the highest proportion milked on record was reported for the United States as a whole. The proportion was very high in all sections and record high percentages milked were reported in the North Central and Western regions. Milk production per cow was above the 10-year average in all major geographical divisions except the South Central States. Increases were reported during June this year in the South Atlantic and Western Regions where the usual seasonal trend is downward, while in other areas slightly more than the normal seasonal decline took place.

For the United States as a whole, milk production per cow in herds kept by crop correspondents averaged 16.77 pounds compared with 16.00 pounds on the same date last year, 16.52 pounds on July 1, 1935 and a 1925-34 average of 16.44 pounds for that date. In the same herds 77.8 percent of the milk cows were reported milked on July 1 compared with 76.7 percent at the same time last year and the previous high record for that date of 77.0 percent in 1930.

CHICKENS and EGGS: The number of young chickens in farm flocks on July 1 is reported 19 percent less than a year ago. This reduction reflects the effect of the relatively high price of feed. Present numbers are the lowest in the 13 year record and well below the low marks set in 1934 and 1935. The decrease during June of 5.2 hens per flock was greater than the decrease of 4.2 hens last year, or the 10-year average June decrease of 3.8 hens. The average number of layers per farm flock remaining on July 1 was only 1.6 percent greater than a year ago and 3.1 percent greater than in July 1935, which latter was the lowest number of layers for July in the record. At the beginning of this year numbers of layers were 4.5 percent greater than a year earlier. The present relatively small number

CROP REPORT

Washington, D. C., July 9, 1937 3:00 P.M. (E.T.)

July 1, 1937.

of layers and the record small number of young birds from which pullets may be secured for replacements indicate that the number of layers in next season's flocks will fall back toward the low levels of 1936 and 1935. Farm flocks continue to register a high rate of production per hen. On July 1, for the third month in succession the number of eggs laid per 100 hens was the record high production for that month in the 13 year record. The large proportion of pullet layers and the close culling are no doubt mainly responsible for the heavy laying. The indicated total production of eggs by farm flocks on July 1 was about 2 percent greater than on that date last year.

^{1/} Averages obtained by dividing the reported daily milk production of herds kept by reporters by the total number of milk cows (in milk or dry) in these herds. The regional averages shown were based in part on records from less important dairy States not shown separately, as follows: South Atlantic, Delaware, Georgia, Florida; South Central, Alabama, Louisiana; Western, New Mexico, Arizona, Utah, Nevada.
